

The Geography of Electoral History: A Dataset of Recent Mexican Election Returns and Quantities of Analytical Interest

Eric Magar
ITAM

January 8, 2025

The advent of competition in Mexican politics produced a wealth of government data for the analysis of public policy and politics. Data is distributed at the municipal level and smaller geographic units of aggregation (such as census tracts or similar levels), and in some cases at the individual level. This has spawned fertile areas of new research in education (Hoyos, Espino and García 2012), public health (Imai, King and Nall 2009; King, Gakidou, Ravishankar, Moore, Lakin, Vargas, Rojo, Ávila, Ávila and Llamas 2007), poverty relief (Díaz Cayeros, Estévez and Magaloni 2016; Molinar Horcasitas and Weldon 1994), legislative politics (Cantú, Desposato and Magar 2014; Rosas and Langston 2011), and electoral regulation (Estévez, Magar and Rosas 2008), to name a few.

1952–1967 1965–1976

This paper's focus are vote returns. Electoral data has been distributed for much longer than the information discussed above. It is also better-known and has received a good deal of attention since seminal studies of the PRI's support bases in the states in federal elections of the 1950s and 1960s (Ames 1970) and the correlation of modernization measures and voting and turnout in federal districts between 1965 and 1976 (Lehr and Pedroza 1985). This paper describes a repository...

Some of the distributed data is elementary and available elsewhere, such as the number of valid votes cast for parties in congressional races since 1991 in single-member districts, in municipalities, and in sub-municipal units of aggregation. shares by party and their change since last election) at the municipal and sub-municipal levels. Offers a cross-section time-series of dip fed returns at two levels of aggregation: municipalities and secciones electorales.

More abstract

from blog

This note presents, discusses, and distributes statistics (available here) of party performance in Mexico's competitive era. I elaborate two quantities of interest: *voting forecasts* based on recent electoral history and measures of parties' *core support*. The procedure produces summary measures of recent electoral history in relatively small geographic units, municipalities ($N \approx 2500$) and /secciones electorales/ ($N \approx 66000$) throughout Mexico. I apply the methodology to four federal congressional elections between 2009 and 2018 (I will soon apply it to municipal races too), using results since 1994 as historical input.

The note starts by showing the statistics in action to get a glimpse of their descriptive and analytic potential. By summarizing recent electoral history and its geography, the quantities offer a scenic view of a critical aspect of contemporary Mexican politics.

Later sections offer methodological detail on the estimation of these quantities of interest and are increasingly technical.

1 Municipal governments

1.1 Policy making authority

Mexico's 2,477 (as of January 2025) *municipios* or *municipio-equivalents*, into which 31 states and Mexico City are subdivided, are the bottom tier of elected governments. Municipal governments have constitutional authority over community police, zoning and construction permits, water supply, sewerage and waste disposal, street lighting, pavement, and park management, and regulate public markets, slaughterhouses, and cemeteries. They appoint municipal staff and subcontract personnel to carry these responsibilities, key sources of patronage in a spoils system, making them links of potential importance to political communities in the maintenance of state and national parties (Key 1964; Sorauf 1959).

Municipalities have authority to collect property taxes and fees from public services but, excepting those with a minimum degree of state capacity (Garfias 2018), they obtain the lion's share of their financial resources from federal revenue sharing and earmarked federal investments (Díaz Cayeros 2006; Figueroa Mansur 2024).

1.2 Government structure

Municipal authority rests in the *Ayuntamiento*, a popularly-elected board deciding by majority rule (Robles Martínez 2009). A municipal council (*cabildo*) and a mayor (*presidente municipal* or *primer regidor*) make up the *Ayuntamiento*. The mayor is executive officer, presides council sessions with voice and the tie-breaking vote, and holds variable municipal appointment powers. Councils, variable in size depending on population, are made up of (1) ranked *regidores* (also called *concejales*), who propose and vote municipal policy through edicts and rulebooks, and (2) possibly one or more *síndicos*, officers in charge of the Treasury and the *municipio's* legal representation. One state at least (Sinaloa, see Ramírez Millán 2000) has no *síndicos*. Where present, *síndicos* can be elected officers, or appointed among *regidores* by the Council. Municipalities have no judicial power. States do.

1.3 Modal electoral institutions

Presidents and *síndicos* (where elected) are elected by plurality. *Regidores* are elected in two groups of variable sizes across states, one group by plurality, the other by proportional representation (Gil Ramírez 2010). With notable exceptions discussed below, municipal officers are elected in fused tickets. Voters have a single vote, which they cast for a list of candidates including a municipal president on top, ranked *regidores*, and possibly *síndicos*. The vote is fused as it simultaneously affects the vote totals of candidates running for different offices (see Cox 1997:42):

the presidency, plurality regidores, and síndicos (where applicable) are allocated to the most voted list. Remaining regidores are distributed to lists proportionally.¹ Split ticket voting is therefore not technically possible.

1.4 Exceptional electoral institutions

the exception of Chihuahua since 1998 and Nayarit since 2008

1.5 Term limits

Municipal governments have three-year terms. Up to 2018, all were single-term limited, like elected officeholders across the board in Mexico since the 1930s. Reformers in 2014 allowed states to opt for two-term limits in their municipalities. All states bar Hidalgo did so, the reform kicking off in 2018 in twenty-three states. Ayuntamiento incumbents in the other eight reforming states have been able run for consecutive reelection gradually since. The last will be in Veracruz's 212 municipalities in 2025.

The reform has the potential as seismic shift in municipal politics. Six consecutive years in office still falls short of qualifying as the long run, but extending Ayuntamientos' time horizons up from just three years should encourage more ambitious policy. More fundamentally, the need to win reelection should encourage ambitious mayors and regidores to keep their electoral alliances alive and mobilized, nurturing responsiveness (Cain, Ferejohn and Fiorina 1987; Cox and McCubbins 1986; Jacobson and Kernell 1983).

The removal of single-term limits was surprising given the Mexican elite's anti-reelection rhetoric and might prove to lack robustness. Morena, the new Goliath of partisan politics since 2018, has repeatedly voiced a will to return to single terms across the board. But the reform offers an interesting laboratory to study institutional change.

1.6 Usos y costumbres

These amount to much fewer formal powers than local governments in other systems. Mexican municipalities have no jurisdiction over public education and health, lack authority to collect other taxes, and must negotiate some fiscal resources with the state government, who may be tempted to bias redistribution of revenue sharing to municipalities (Timmons and Broid 2013)

Still, the institutional heterogeneity and variable socio-economic conditions make them very interesting for social science.

But interest in Mexico's municipal government has nonetheless grown

But, with much heterogeneity, municipal governments grew in importance between 1990 and 2010. Percent of public spending they exert... making them, and the variance they manifest, attractive areas for the study of politics and policy.

¹As of 2010, the mean Ayuntamiento had two-thirds of majority seats, with considerable variance. Guanajuato's municipalities, the lowest, had 20 percent. Tabasco's, the highest, had 81 percent. See Gil Ramírez (2010:14).

2 The data

Repository has more.

This research note introduces a dataset of municipal election vote returns that has been under construction for some time. The original seed for the 1970s and 1980s was compiled by Molinar (1991) from the Registro Nacional de Electores of the Interior Ministry’s official returns. The primary source was systematized by Magar (1994) for northern Mexico and then by Varela (2004) nationwide. Data from the 1990s onwards was compiled from the new state election regulators, who more or less routinely report vote returns since. When that was not the case, other sources were consulted, most notably *Voz y voto : política y elecciones* (1993) and *Centro de Estudios de la Democracia y Elecciones* (1991).

The unit of observation is the municipality (*municipio* in Spanish), reporting votes won by each party or electoral coalition in periodic elections.

Data is available in a handful of states since the early 1970s, but the full cross-sectional time-series in the dataset really begins in the 1979–1981 trienium. This period, inaugurated by a major federal electoral reform (the LFOPPE), lowered legal entry barriers and adopted a more proportional electoral formula in Congress (Molinar 1991:116). As a result, half a dozen new parties entered the electoral arena. Table 1 summarizes data coverage by state, reporting the number of municipalities (which increased over the years in most states)²

3 Reelection as insurance policy

Also discusses another dataset in the repository, incumbents.

4 The measurement of electoral history

Also discusses another dataset in the repository, whats.

5 Non-fused tickets in Nayarit

Also discusses another dataset in the repository, nayreg.

Table [[fig:1]] presents two pairs of diagrams for the 2015 (below) and 2018 (above) congressional elections. Each dot represents one municipality, colored according to the winning party, with coordinates in the ternary plot according to the relative votes of the PAN, the PRI, and the left in the federal deputy race (other smaller parties are excluded).³

The left side shows the /vote forecasts/. The idea behind this statistic is summarizing the evolution of relative votes in the municipality in five previous elections (2003–2015 in the case of

²File `ancillary/mun.yrs.csv` in the repository reports the full listing of municipalities in each election cycle with available municipal election returns. And file `ancillary/new-mun-parents-1989on.csv` reports the parent municipalities from which the new units seceded.

³I must note that, for the left’s electoral history (which I arbitrarily call “Morena” in the plots and distributed data), I systematically added up the votes of the PRD, PT, and MC up to 2015. I also added Morena’s and PES’s votes that year. In 2018 the left consisted of Morena, PT, and PES jointly.

	State (abbreviation)	Number of municipalities	Years
1	Aguascalientes (ags)	9–11	1977–2024
2	Baja California (bc)	4–7	1971–2024
3	Baja California Sur (bcs)	3–5	1974–2024

	Municipalities nationwide by election cycle	2375–2477	1970–2024

Table 1: Coverage of the election returns data at the municipal level. [†] Reform in these states withdrew so-called ‘usos y costumbres’ municipalities from the periodic electoral process: one municipality in Chiapas since 2021, one in Guerrero since 2018 and another since 2024, one in Michoacán since 2011, three in Morelos since 2021, and between 412 and 418 in Oaxaca since 1995. [‡] Administrative jurisdictions in the Federal District became elected offices since 1997.

2018) and using the tendency to project a vote forecast for the current year. Plots in the right side show the actual results observed in both elections.

Three features are noteworthy in 2018. The first is the discrepancy between the left and right plots. Either the model does a poor job forecasting, or 2018 was an extraordinary election. History gave license to expect a comfortable PRI victory, both in the number of municipalities won and in margins of victory. Municipalities outside the dotted bands are won by margins of 15 points or more, and the bulk of secure municipalities are red in the forecast, with Morena in a distant second place. In fact, although a significant number of municipalities migrated towards the PAN, it was Morena who showed a clear advantage. PRI was the underachiever. In contrast, the lower left and right plots reveal fewer differences between them—2015 was a more normal election, the past offering much better grounds to forecast.

Second, observed municipalities fled the edges and triangle vertices in 2018. Observations in vertices show a party that has no significant challenger. While those on the edges were bipartisan, whether more (inside dotted bands) or less (outside the bands) symmetric. It is also plain in forecasts that only the PAN–Morena edge was expected to be unpopulated. In practice, however, third party vote rarely collapsed to zero, there was much more dis-coordination than in the past. In fact, the intersection of dotted bands appeared denser and more homogeneous in the right than the left diagram.

Third, the PAN /vs/ left competition was legal tender in 2018. The pattern in competitive municipalities in the last two decades, still visible in the 2015 plots, involved either PRI–PAN or PRI–left rivalries, and rarely PAN–izquierda. It was this pattern that eased electoral alliances between PAN and PRD in sub national races since 2010 that culminated in the Frente they formed in 2018 to nominate a joint presidential candidate.

Plots in Table [[fig:4]] report /secciones electorales/ and therefore offer much finer-grained than the previous portraits. They introduce the other quantity of interest in this note: parties' /core support/. The idea behind this statistic is measuring the size of the group that has historically supported the party consistently, in good but also in bad years.

The horizontal axis in each plot measures the size of party core support groups as a proportion of the /sección/'s electorate. The PRI enjoyed a clear edge over the rest of the parties in the period, with sizable cores in /all/ secciones nationwide. The distributions of the PAN and the left, in contrast, appear concentrated towards the zero—they have relatively few secciones with some unconditional support.

The vertical axis reports the three parties' performance in 2018 (the difference between the observed vote and the forecast). Positive values indicate that the party excelled expectations in the /sección/, negative ones that it under-performed it expectation. The PRI's electoral disaster appears all too clearly in the red plot. There were a few secciones with positive performance, but the density concentrates massively below the horizontal zero line, something that Table [[fig:1]] had hinted. What is truly remarkable is that the dismal performance is directly proportional to the size of the PRI core. President Peña and candidate Meade achieved what seemed, if not impossible, extremely improbable: they alienated the PRI's unconditional voters in 2018. The PAN and the left met expectations in secciones where they have enjoyed with groups of support. Both (especially Morena) over-achieved where they lack important cores, taking away PRI voters.

The note elaborates how statistics were prepared (replication code can be found [[<https://github.com/emagar/mexico-data-for-maps.r>]][here]]).

* First differences One common approach to study electoral change is through first differences.

Denoting v_t the party's vote share in the municipality or the /sección/, in period t , the first difference is simply $d_t = v_t - v_{t-1}$.

d_t is an intuitive quantity, showing the sign and magnitude of change from one election to the next. But, precisely because it compares pairs of consecutive elections only, it misses more dynamic processes in the units. One example, well documented by electoral sociology, is the regression to the mean (Campbell 1991; Segovia 1979). Its detection requires observing the unit through at least three consecutive periods to verify contrary signs in d_{t+1} and d_t . The study of secular change in the Mexican party system in the last quarter of century calls for deeper historical perspective.

(First differences appear in the fields `d.pan`, `d.pri`, and `d.morena` in the distributed data.)

* The recent linear tendency One way of adopting it is with /vote forecasting/ from tendencies discernible in the previous five congressional races (Magar 2012). I summarize the central tendency of the recent historical vote by means of linear estimation in time, fitting a straight line for each year analyzed and each party in the municipality or /sección electoral/.

The slope of the fitted line (the tendency) serves to extrapolate the party's electoral support to the future. For instance, to get the vote share that the recent past predicts for a party in unit u for 2018, I estimate the following equation

$$v_{ut} = a_u + b_u \times t + \text{error}_{ut}, \quad t = 2003, \dots, 2015 \quad (1)$$

that I then use to predict $\hat{v}_{u2018} = \hat{a}_u + \hat{b}_u \times 2018$. This is an out-of-sample prediction of the party's vote share, it can be compared to the party's actual vote share in 2018 to gauge whether or not the unit approximates the historical record. For the 2015 forecast the sample shifts one period to become $t = 2000, \dots, 2012$, and so on an so forth for previous years. I distribute forecasts for 2009, 2012, 2015, and 2018, which involved fitting about 10 thousand municipal regressions and more than 250 thousand sección-level.

(Vote forecasts appear in the fields `vhat.pan`, `vhat.pri`, and `vhat.morena` of the distributed data.)

* The party's support core The other historical statistic is the parties' core support in the unit. Its definition stems from classifying voters in three categories: (1) support groups, that in the past have consistently supported the party; (2) opposition groups, that have consistently supported another party; and (3) swing groups, that have neither consistently supported nor consistently opposed the party (Cox and McCubbins 1986). The party core consists of the support groups.

I use the procedure by Díaz Cayeros /et al/. (2016) to estimate this core. If \bar{v}_t denotes the party's mean support across all units in period t ,⁴ for each party in each unit I fit

$$v_{ut} = \alpha_u + \beta_u \times \bar{v}_t + \text{error}_{ut}, \quad t = 1994, \dots, 2018. \quad (2)$$

β_u measures the effect that national party tides have on the party's vote in unit u . For instance, $\hat{\beta}_u = 1$ estimates that for every percentage point that the party wins or loses nationally in year t ,

⁴The analyzed unit u should be dropped from period t 's mean in order to not include the dependent variable in the right side of equation 5. I do not drop it due to the large number of municipal or seccional units (each contributing a fraction to the mean) and the use of vote shares (so large units are watered down): this refinement's impact should be negligible in each mean value.

it also wins or loses one percentage point in the unit; $\hat{\beta}_u = 0$, on the other hand, would indicate the unit's full isolation from national swings. It is therefore a measure of party volatility in the municipality or /sección/ (analogous to "beta volatility" in the financial literature).

The α coefficient estimates the core size: expected support in unit u in the hypothetical case that the party receives no vote at the national level. For instance, $\hat{\alpha} = .4$ would indicate that, in the starkest of scenarios, 40

A critique that can be anticipated towards this measure of the party's support core is its extreme counter-factual nature (King and Zeng 2006). It deserves rigorous scrutiny, something I plan doing in the near future.

(The parties' core support appears in the fields `alphahat.pan`, `alphahat.pri`, and `alphahat.morena` of the distributed data. Party volatility in `betahat.pan`, `betahat.pri`, and `betahat.morena`.)

* Compositional variables I close with an important feature of the model specifications, associated with the *compositional* nature of electoral returns. Compositional variables are quantitative descriptions of the parts of a whole. They therefore have two characteristics: (1) they are proportions that (2) add up to unity.⁵

When estimating parties separately, the challenge of equations 1 and 2 is to avoid forecasting vote shares less than zero or greater than one; and that the sum of party forecasts equals 1. To achieve this, Aitchison (1986) proposes substituting vote shares by log-ratios in the analysis. Arbitrarily setting the PRI as the reference party, define party p 's vote relative to the PRI as

$$r_p = \frac{v_p}{v_{\text{pri}}}.$$

A value $r_p = 1$ would indicate a tie between the party and the PRI, while $r_p > 1$ that it finished ahead of the PRI in the proportion that the value reveals.

Thus, equation 1 is re-specified as

$$\ln r_{put} = a + b \times t + \text{error}$$

by equation 2 as

$$\ln r_{put} = \alpha + \beta \times \bar{r}_{pt} + \text{error}.$$

Applying the natural logarithm attenuates the effect of extreme values of the regressor on the dependent variable, similar as a logit regression would. Models fitting was done with ordinary least squares.

Coefficient estimates requires transformation to collect party vote shares. Illustrating with a three-party caste, it is trivial that

$$\hat{v}_p = \frac{\hat{r}_p}{1 + \hat{r}_{\text{pan}} + \hat{r}_{\text{morena}}} \text{ and } \hat{v}_{\text{pri}} = \frac{1}{1 + \hat{r}_{\text{pan}} + \hat{r}_{\text{morena}}}. \quad (3)$$

These are the quantities that the distributed data report.
